04-Feb-2018 The AKVIS SDK v.2018.1.0 for Erdas Imagine is an .Intermediate-term outcomes following the CyberKnife procedure in patients with spinal metastases: report from the CyberKnife registry and review of the literature. Although the CyberKnife (CK) has been used widely to treat patients with spinal metastases, there are few studies regarding intermediate-term efficacy and toxicity. The purpose of this study was to report outcomes of patients with spinal metastases treated with CK. Patients treated with CK for spinal metastases between April 2001 and December 2011 were identified. Baseline characteristics, treatment parameters, complications, and outcomes were retrospectively collected. Overall survival (OS), progression-free survival (PFS), and local control (LC) were estimated using the Kaplan-Meier method. Univariate and multivariate Cox regression analysis were performed to identify risk factors associated with PFS and OS. One hundred seventy-two patients were included in the study. The median follow-up was 12.7 months (range, 0.4-158.5 months), and the median LC was 12.5 months (range, 0-158.5 months). The 3- and 5-year OS rates were 41.4 and 17.7%, and the PFS rate was 23.1 and 15.1%, respectively. The 3- and 5-year LC rates were 56.5 and 35.2%, respectively. Symptomatic control, ambulatory status, and intracranial control were significant factors associated with OS. The presence of local and systemic progression was the only significant factor associated with LC. The most common toxicities were Grade 1 and 2 radiation myelitis (15.7% and 4.8%, respectively). Overall, 5.4% of patients had Grade 3-4 toxicities. CK is a safe and effective treatment for patients with spinal metastases. The OS of patients treated with CK was modest but was associated with favorable local and intracranial control. We're very proud to announce a new solo album from the great Aron Wagner!
