**Leveraging the Mouse** The computer mouse was invented by psychologist Melvin C. Steele at the University of California, Berkeley in 1971, and was made commercially available in 1977. Steele was dissatisfied with existing solutions for drawing and drafting software, and he wanted to create a device that could be used to control the mouse pointer without having to move a finger or stylus. The problem Steele had to solve was making a device that could be used to move the mouse pointer, but not be considered an input device, such as a typewriter or a joystick. This is different from a mouse, which we use to move a pointer. Steele's mouse solved that problem by using a

design that allowed the ball of the mouse to move freely over a surface in two dimensions, but also to move in the other two dimensions when the ball of the mouse was lifted off the surface. In addition, there was an internal potentiometer that told the computer where the user was on the surface, and how far the user had moved the ball. Steele thought up the idea for the mouse at the time because he was looking for a way to use his computer mouse, but it eventually was adopted by many other developers of drawing and drafting software. Mouse as a Mouse Steele's mouse helped to increase the adoption of computers for drafting and design, but it did not greatly increase the use of computers in drafting and design. One reason is that the size of the mouse ball (the knurled wheel) was too small. This meant that a user had to pick up the mouse and lift the ball to use the mouse. If the user had to move the mouse that far, then it was unlikely that the user would pick up the mouse every time he or she wanted to use the mouse. The other reason is that the mouse was not seen as an input device. When users had to lift the mouse, they were not using the mouse as a pointing device. Also, there were no gestures or other

input actions (such as "click") that could be mapped to the mouse. Because of these limitations, drawing and drafting programs using the mouse as the input device did not become popular until much later. But it was soon evident that a larger mouse ball was needed for use with larger mice. One of the first mice that could be used with larger balls was the high-quality Smith Mouse. In 1984, the Tracing-Plotter Tool Box, and the Steering Wheel tool
